## Question 1

(a)

The directed acyclic graph:

(b)

The moralised graph:

An effective triangulation:

where the dashed lines are edges added to triangulate the moralised graph.

The resulting junction tree:

where the circular nodes are cliques.

The junction tree redrawn as a factor graph:

where the circular nodes are cliques and the square nodes are separators/factors.

(c)

The set  $\{A, D, E, F, H\}$  is a non-unique smallest set of molecules such that if the concentrations of the species within the set are known, the concentrations of the others  $\{B, C, G, I\}$  would all be independent (conditioned on the measured ones).

(d)

(e)

## Question 2

(a)

We want the posterior mean and covariance over a and b. Defining a weight vector  $\mathbf{w}$ :

$$\mathbf{w} = \begin{bmatrix} a \\ b \end{bmatrix}$$

Our distribution for w:

$$P(\mathbf{w}) = \mathcal{N}\left(\begin{bmatrix} \mu_a \\ \mu_b \end{bmatrix}, \begin{bmatrix} \sigma_a^2 & 0 \\ 0 & \sigma_b^2 \end{bmatrix}\right) = \mathcal{N}(\mu_\mathbf{w}, \Sigma_\mathbf{w})$$

Moreover, for our data  $\mathcal{D} = \{X, Y\}$ :

$$P(\mathcal{D}|\mathbf{w}) = \mathcal{N}\left(\mathbf{Y} - \mathbf{w}^T \mathbf{X}, \sigma^2 \mathbf{I}\right)$$

where 
$$\mathbf{X} = \begin{bmatrix} t_1 & t_2 \cdots t_N \\ 1 & 1 \cdots 1 \end{bmatrix} \in \mathbb{R}^{2 \times N}$$
 and  $\mathbf{Y} \in \mathbb{R}^{1 \times N}$ .

Knowing:

$$P(\mathbf{w}|\mathcal{D}) \propto P(\mathcal{D}|\mathbf{w})P(\mathbf{w})$$

we can substitute the above distributions:

$$P(\mathbf{w}|\mathcal{D}) \propto \exp\left(\frac{-1}{2\sigma^2} \left(\mathbf{Y} - \mathbf{w}^T \mathbf{X}\right) \left(\mathbf{Y} - \mathbf{w}^T \mathbf{X}\right)^T\right) \exp\left(\frac{-1}{2} \left(\mathbf{w} - \mu_{\mathbf{w}}\right)^T \Sigma_{\mathbf{w}}^{-1} \left(\mathbf{w} - \mu_{\mathbf{w}}\right)\right)$$

expanding:

$$\log P(\mathbf{w}|\mathcal{D}) \propto \frac{-1}{2} \left( \frac{\mathbf{Y}\mathbf{Y}^T}{\sigma^2} - 2\mathbf{w}^T \frac{\mathbf{X}\mathbf{Y}^T}{\sigma^2} + \mathbf{w}^T \frac{\mathbf{X}\mathbf{X}^T}{\sigma^2} \mathbf{w} + \mathbf{w}^T \boldsymbol{\Sigma}_{\mathbf{w}}^{-1} \mathbf{w} - 2\mathbf{w}^T \boldsymbol{\Sigma}_{\mathbf{w}}^{-1} \boldsymbol{\mu}_{\mathbf{w}} + \boldsymbol{\mu}_{\mathbf{w}}^T \boldsymbol{\Sigma}_{\mathbf{w}}^{-1} \boldsymbol{\mu}_{\mathbf{w}} \right)$$

collecting w terms:

$$\log P(\mathbf{w}|\mathcal{D}) \propto \frac{-1}{2} \left( \mathbf{w}^T \left( \frac{\mathbf{X} \mathbf{X}^T}{\sigma^2} + \Sigma_{\mathbf{w}}^{-1} \right) \mathbf{w} - 2 \mathbf{w}^T \left( \frac{\mathbf{X} \mathbf{Y}^T}{\sigma^2} + \Sigma_{\mathbf{w}}^{-1} \mu_{\mathbf{w}} \right) \right)$$

Knowing that the posterior  $P(\mathbf{w}|\mathcal{D})$  will be Gaussian with mean  $\bar{\mu}_w$  and covariance  $\bar{\Sigma}_w$ , we can see that expanding the exponent component would have the form:

$$(\mathbf{w} - \bar{\mu}_w)^T \bar{\Sigma}_w^{-1} (\mathbf{w} - \bar{\mu}_w) = \mathbf{w}^T \bar{\Sigma}_w^{-1} \mathbf{w} - 2\mathbf{w}^T \bar{\Sigma}_w^{-1} \bar{\mu}_w + \bar{\mu}_w^T \bar{\Sigma}_w^{-1} \bar{\mu}_w$$

Thus we can identify the posterior covariance:

$$\bar{\Sigma}_w = \left(\frac{\mathbf{X}\mathbf{X}^T}{\sigma^2} + \Sigma_{\mathbf{w}}^{-1}\right)^{-1}$$

and the posterior mean:

$$\bar{\mu}_w = \bar{\Sigma}_w \left( \frac{\mathbf{X} \mathbf{Y}^T}{\sigma^2} + \Sigma_{\mathbf{w}}^{-1} \mu_{\mathbf{w}} \right)$$

Computing the posterior mean and covariance over a and b given by the  $CO_2$  data:

|           |   | value      |
|-----------|---|------------|
| arameters | а | 1.828457   |
|           | _ |            |
|           | b | 334.203782 |
|           |   |            |

Figure 1: The Posterior Mean

Figure 2: t=The Posterior Covariance

(b)

Plotting the residuals:

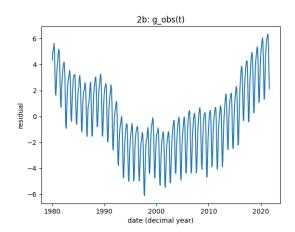

Figure 3:  $g_{obs}(t)$ 

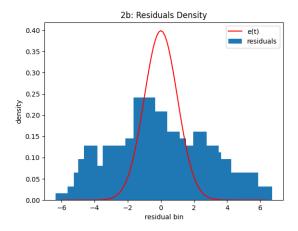

Figure 4: Density Estimation of Residuals vs  $e(t) \sim \mathcal{N}(0,1)$ 

We can see that the residuals do not perfectly conform to our prior over  $e(t) \sim \mathcal{N}(0,1)$ . The density estimation shows that a mean of zero is a reasonable prior belief however the data does not seem to exhibit unit variance.

(c & d)

We are considering the kernel:

$$k(s,t) = \theta^2 \left( \exp\left(-\frac{2\sin^2(\pi(s-t)/\tau)}{\sigma^2}\right) + \phi^2 \exp\left(-\frac{(s-t)^2}{2\eta^2}\right) \right) + \zeta^2 \delta_{s=t}$$

We can make qualitative observations this kernel by visualising the covariance (gram) matrix:

Figure 5: Gram Matrix

We can observe a striped pattern which indicate higher covariance at regular intervals. This can be attributed to the sinusoidal term in the kernel and encourages sinusoidal functions. Additionally, we can see that covariance values also decay as they are further away from the diagonal. This can be attributed to the exponential term in the kernel, encouraging points closer in time to be more correlated and vice versa. From our  $CO_2$  data, we would want a class of functions which exhibit both of these behaviours as the data looks sinusoidal (seasonal with respect to each year) and correlations locally.

We can also visualise some samples from a Gaussian Process with the same covariance matrix and zero mean. This verifies our observations about the covariance matrix.

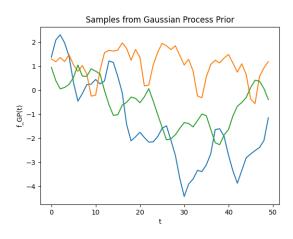

Figure 6: Samples from a zero mean GP with the provided covariance kernel

More specifically, we can see how changing each hyper-parameter will affect the characteristics of the function.

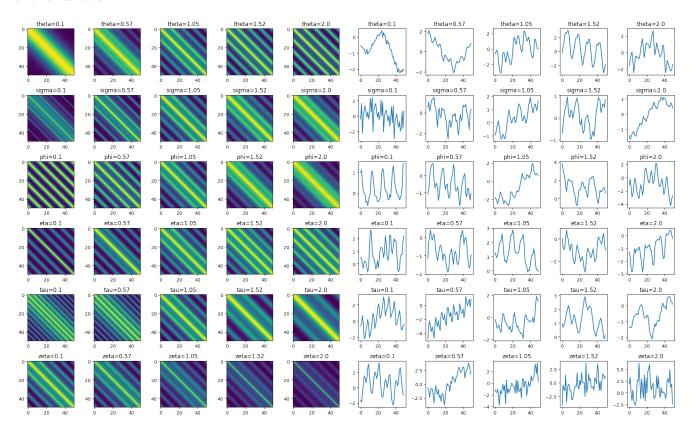

Figure 7: Covariances for different parameters

 $\eta$ :

 $\tau$ :

 $\zeta$ :

Figure 8: Samples for different parameters

- $\theta$ : As  $\theta$  increases, we see more pronounced periodic behavior in the sample function. The covariance matrix shows how increasing  $\theta$  visually reveals the striped periodic component. This is expected because it is the parameter that adjusts the weight of  $\exp\left(-\frac{2\sin^2(\pi(s-t)/\tau)}{\sigma^2}\right)$ .
- $\sigma$ : As  $\sigma$  increases, we see smoother periodic behaviour in the sample function. The covariance matrix shows how increasing  $\sigma$  will increase covariance values in the off-diagonals. This is expected because it adjusts the lengthscale of the periodic portion of the kernel.
- $\phi$ : As  $\phi$  increases, we see less smooth behaviour in the sample function. The covariance matrix shows how increasing  $\sigma$  will increase covariance values in the off-diagonals. This is expected because it adjusts the lengthscale of the periodic portion of the kernel.

## Question 3

(a)

The free energy is can be calculated as:

$$\mathcal{F}(q, \theta) = \langle \log P(\mathbf{x}, \mathbf{s} | \theta) \rangle_{q(\mathbf{s})} + H[Q(\mathbf{s})]$$

Knowing,

$$\log P(\mathbf{x}, \mathbf{s}|\theta) = \log P(\mathbf{x}|\mathbf{s}, \theta) + \log P(\mathbf{s}|\theta)$$

we can write:

$$\mathcal{F}(Q, \theta) = \langle \log P(\mathbf{x}|\mathbf{s}, \theta) \rangle_{q(\mathbf{s})} + \langle \log P(\mathbf{s}|\theta) \rangle_{q(\mathbf{s})} + H[q(\mathbf{s})]$$

Moreover, our mean field approximation:

$$q(\mathbf{s}) = \prod_{i=1}^{K} q_i(s_i)$$

where  $q_i(s_i) = \lambda_i^{s_i} (1 - \lambda_i)^{(1-s_i)}$ .

To compute the first term:

$$P(\mathbf{x}|\mathbf{s}, \theta) = \mathcal{N}\left(\sum_{i=1}^{K} s_i \mu_i, \sigma^2 \mathbf{I}\right)$$

substituting the appropriate terms:

$$P(\mathbf{x}|\mathbf{s}, \theta) = 2\pi^{-\frac{d}{2}} |\sigma^2 \mathbf{I}|^{-\frac{1}{2}} \exp\left(-\frac{1}{2} \left(\mathbf{x} - \sum_{i=1}^K s_i \mu_i\right)^T \frac{1}{\sigma^2} \mathbf{I} \left(\mathbf{x} - \sum_{i=1}^K s_i \mu_i\right)\right)$$

with d being the number of dimensions.

Taking the logarithm:

$$\log P(\mathbf{x}|\mathbf{s}, \theta) = -\frac{d}{2}\log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \left(\mathbf{x}^T\mathbf{x} - 2\mathbf{x}^T\sum_{i=1}^K s_i\mu_i + \sum_{i=1}^K\sum_{j=1}^K s_is_j\mu_i^T\mu_j\right)$$

The expectation distributed to the relevant terms:

$$\langle \log P(\mathbf{x}|\mathbf{s}, \theta) \rangle_{q(\mathbf{s})} = -\frac{d}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \left( \mathbf{x}^T \mathbf{x} - 2\mathbf{x}^T \sum_{i=1}^K \langle s_i \rangle_{q_i(s_i)} \mu_i + \sum_{i=1}^K \sum_{j=1}^K \langle s_i s_j \rangle_{q_i(s_i)q_j(s_j)} \mu_i^T \mu_j \right)$$

Evaluating the expectations:

$$\langle \log P(\mathbf{x}|\mathbf{s}, \theta) \rangle_{q(\mathbf{s})} = -\frac{d}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \left( \mathbf{x}^T \mathbf{x} - 2\mathbf{x}^T \sum_{i=1}^K \lambda_i \mu_i + \sum_{i=1}^K \sum_{j=1, j \neq i}^K \lambda_i \lambda_j \mu_i^T \mu_j + \sum_{i=1}^K \lambda_i \mu_i^T \mu_i \right)$$

where  $\langle s_i s_i \rangle_{q_i(s_i)} = \langle s_i \rangle_{q_i(s_i)}$  because  $s_i \in \{0, 1\}$ .

To compute the second term:

$$P(\mathbf{s}|\theta) = \prod_{i=1}^{K} \pi_i^{s_i} (1 - \pi_i)^{(1-s_i)}$$

Taking the logarithm:

$$\log P(\mathbf{s}|\theta) = \sum_{i=1}^{K} s_i \log \pi_i + (1 - s_i) \log(1 - \pi_i)$$

The expectation distributed to the relevant terms:

$$\langle \log P(\mathbf{s}|\theta) \rangle_{q(\mathbf{s})} = \sum_{i=1}^{K} \langle s_i \rangle_{q_i(s_i)} \log \pi_i + (1 - \langle s_i \rangle_{q_i(s_i)}) \log(1 - \pi_i)$$

Evaluating the expectations:

$$\langle \log P(\mathbf{s}|\theta) \rangle_{q(\mathbf{s})} = \sum_{i=1}^{K} \lambda_i \log \pi_i + (1 - \lambda_i) \log(1 - \pi_i)$$

To compute the third term, we use the mean field factorisation:

$$H\left[q(\mathbf{s})\right] = \sum_{i=1}^{K} H\left[q_i(s_i)\right]$$

Thus,

$$H[q(\mathbf{s})] = -\sum_{i=1}^{K} \sum_{s_i \in \{0,1\}} q_i(s_i) \log q_i(s_i)$$

Substituting the appropriate values:

$$H[q(\mathbf{s})] = -\sum_{i=1}^{K} \lambda_i \log \lambda_i + (1 - \lambda_i) \log(1 - \lambda_i)$$

Combining, we have our free energy expression:

$$\begin{aligned} \mathcal{F}(q,\theta) &= \\ &\frac{-d}{2} \log(2\pi\sigma^2) - \frac{1}{2\sigma^2} \left( \mathbf{x}^T \mathbf{x} - 2\mathbf{x}^T \sum_{i=1}^K \lambda_i \mu_i + \sum_{i=1}^K \sum_{j=1, j \neq i}^K \lambda_i \lambda_j \mu_i^T \mu_j + \sum_{i=1}^K \lambda_i \mu_i^T \mu_i \right) \\ &+ \sum_{i=1}^K \lambda_i \log \pi_i + (1 - \lambda_i) \log(1 - \pi_i) \\ &- \sum_{i=1}^K \lambda_i \log \lambda_i + (1 - \lambda_i) \log(1 - \lambda_i) \end{aligned}$$

To derive the partial update for  $q_i(s_i)$  we take the variational derivative of the Lagrangian, enforcing the normalisation of  $q_i$ :

$$\frac{\partial}{\partial q_i} \left( \mathcal{F}(q, \theta) + \lambda^{LG} \int q_i - 1 \right) = \langle \log P(\mathbf{x}, \mathbf{s} | \theta) \rangle_{\prod_{j \neq i} q_j(s_j)} - \log q_i(s_i) - 1 + \lambda^{LG}$$

where  $\lambda^{LG}$  is the Lagrange multiplier.

Setting this to zero we can solve for the  $\lambda_i$  that maximises the free energy:

$$\log q_i(s_i) = \langle \log P(\mathbf{x}, \mathbf{s} | \theta) \rangle_{\prod_{i \neq i} q_i(s_i)} - 1 + \lambda^{LG}$$

Similar to our free energy derivation:

$$\langle \log P(\mathbf{x}|\mathbf{s}, \theta) \rangle_{\prod_{j \neq i} q_j(s_j)} \propto -\frac{1}{2\sigma^2} \left( \mathbf{x}^T \mathbf{x} - 2\mathbf{x}^T \sum_{k=1}^K \langle s_k \rangle_{\prod_{j \neq i} q_j(s_j)} \mu_i + \sum_{k=1}^K \sum_{j=1}^K \langle s_k s_j \rangle_{\prod_{j \neq i} q_j(s_j)} \right)$$

and

$$\langle \log P(\mathbf{s}|\theta) \rangle_{\prod_{j \neq i} q_j(s_j)} = \sum_{k=1}^K \langle s_k \rangle_{\prod_{j \neq i} q_j(s_j)} \log \pi_k + (1 - \langle s_k \rangle_{\prod_{j \neq i} q_j(s_j)}) \log(1 - \pi_k)$$

We can write:

$$\log q_i(s_i) \propto \log P(\mathbf{x}|\mathbf{s}, \theta) \rangle_{\prod_{j \neq i} q_j(s_j)} + \langle \log P(\mathbf{s}|\theta) \rangle_{\prod_{j \neq i} q_j(s_j)}$$

Substituting the relevant terms:

$$\log q_i(s_i) \propto -\frac{1}{2\sigma^2} \left( -2s_i \mathbf{x}^T \mu_i + s_i s_i \mu_i^T \mu_i + 2 \sum_{j=1, j \neq i}^K s_i \lambda_j \mu_i^T \mu_j \right) + s_i \log \pi_i + (1 - s_i) \log(1 - \pi_i)$$

Knowing  $\log q_i(s_i) = s_i \log \lambda_i + (1 - s_i) \log(1 - \lambda_i)$ :

$$\log q_i(s_i) \propto s_i \log \frac{\lambda_i}{1 - \lambda_i}$$

Thus,

$$s_i \log \frac{\lambda_i}{1 - \lambda_i} \propto -\frac{1}{2\sigma^2} \left( -2s_i \mathbf{x}^T \mu_i + s_i s_i \mu_i^T \mu_i + 2 \sum_{j=1, j \neq i}^K s_i \lambda_j \mu_i^T \mu_j \right) + s_i \log \frac{\pi_i}{1 - \pi_i}$$

Also, because  $s_i \in \{0, 1\}$  we know that  $s_i^2 = s_i$ :

$$s_i \log \frac{\lambda_i}{1 - \lambda_i} \propto -\frac{1}{2\sigma^2} \left( -2s_i \mathbf{x}^T \mu_i + s_i \mu_i^T \mu_i + 2 \sum_{j=1, j \neq i}^K s_i \lambda_j \mu_i^T \mu_j \right) + s_i \log \frac{\pi_i}{1 - \pi_i}$$

Because we have only kept terms with  $s_i$ , this is an equality:

$$s_i \log \frac{\lambda_i}{1 - \lambda_i} = \frac{s_i \mu_i^T}{2\sigma^2} \left( 2\mathbf{x} - \mu_i - 2\sum_{j=1, j \neq i}^K \lambda_j \mu_j \right) + s_i \log \frac{\pi_i}{1 - \pi_i}$$

Solving for  $\lambda_i$ :

$$\lambda_i = \frac{1}{1 + \exp\left[-\left(\frac{\mu_i^T}{\sigma^2} \left(\mathbf{x} - \frac{\mu_i}{2} - \sum_{j=1, j \neq i}^K \lambda_j \mu_j\right) + \log\frac{\pi_i}{1 - \pi_i}\right)\right]}$$

we have our partial update.

# Question 4

### Question 5

(a)

The log-joint probability for a single observation-source pair:

$$\log p(\mathbf{s}, \mathbf{x}) = \log p(\mathbf{s}) + (\mathbf{x}|\mathbf{s})$$

Knowing  $p(\mathbf{s}) = \prod_{i=1}^K p(s_i|\pi_i)$  and  $p(\mathbf{x}|\mathbf{s}) = \mathcal{N}(\sum_{i=1}^K s_i \mu_i, \sigma^2 \mathbf{I})$ :

$$\log p(\mathbf{s}, \mathbf{x}) \propto \frac{-1}{2} \left( \mathbf{x} - \sum_{i=1}^{K} s_i \mu_i \right)^T \frac{1}{\sigma^2} \mathbf{I} \left( \mathbf{x} - \sum_{i=1}^{K} s_i \mu_i \right) + \sum_{i=1}^{K} \left( s_i \log \pi_i + (1 - s_i) \log(1 - \pi_i) \right)$$

Expanding:

$$\log p(\mathbf{s}, \mathbf{x}) \propto \frac{-1}{2\sigma^2} \left( \mathbf{x}^T \mathbf{x} - 2\mathbf{x}^T \sum_{i=1}^K s_i \mu_i + \sum_{i=1}^K \sum_{j=1}^K s_i s_j \mu_i^T \mu_j \right) + \sum_{i=1}^K \left( s_i \log \pi_i + (1 - s_i) \log(1 - \pi_i) \right)$$

Collecting terms pertaining to  $s_i$ :

$$\log p(\mathbf{s}, \mathbf{x}) = \sum_{i=1}^{K} \left( \left( \frac{\mathbf{x}^T \mu_i}{\sigma^2} + \log \frac{\pi_i}{1 - \pi_i} \right) s_i \right) + \sum_{i=1}^{K} \sum_{j=1}^{K} \left( \frac{-\mu_i^T \mu_j}{2\sigma^2} s_i s_j \right) + C$$

where C are all other terms without  $s_i$ .

Knowing that  $s_i^2 = s_i$ :

$$\log p(\mathbf{s}, \mathbf{x}) = \sum_{i=1}^{K} \left( \left( \frac{\mathbf{x}^{T} \mu_{i}}{\sigma^{2}} + \log \frac{\pi_{i}}{1 - \pi_{i}} - \frac{\mu_{i}^{T} \mu_{j}}{2\sigma^{2}} \right) s_{i} \right) + \sum_{i=1}^{K} \sum_{j=1}^{i-1} \left( \frac{-\mu_{i}^{T} \mu_{j}}{\sigma^{2}} s_{i} s_{j} \right) + C$$

Thus:

$$\log p(\mathbf{s}, \mathbf{x}) = \sum_{i=1}^{K} \log f_i(s_i) + \sum_{i=1}^{K} \sum_{j=1}^{i-1} \log g_{ij}(s_i, s_j)$$

where the factors are defined:

$$\log f_i(s_i) = \left(\frac{\mathbf{x}^T \mu_i}{\sigma^2} + \log \frac{\pi_i}{1 - \pi_i} - \frac{\mu_i^T \mu_j}{2\sigma^2}\right) s_i$$

and

$$\log g_{ij}(s_i, s_j) = \frac{-\mu_i^T \mu_j}{\sigma^2} s_i s_j$$

as required. Note that C can simply be absorbed into any one of these factors. The Boltzmann Machine can be defined:

$$P(\mathbf{s}|\mathbf{W}, \mathbf{b}) = \frac{1}{Z} \exp\left(\sum_{i=1}^{K} \sum_{j=1}^{i-1} W_{ij} s_i s_j - \sum_{i=1}^{K} b_i s_i\right)$$

where  $s_i \in \{0, 1\}$ , the same as our source variables. From our factorisation, we can see that  $p(\mathbf{s}, \mathbf{x})$  is a Boltzmann Machine with:

$$W_{ij} = \frac{-\mu_i^T \mu_j}{\sigma^2}$$

and

$$b_i = -\left(\frac{\mathbf{x}^T \mu_i}{\sigma^2} + \log \frac{\pi_i}{1 - \pi_i} - \frac{\mu_i^T \mu_j}{2\sigma^2}\right)$$

and

$$\log Z = -C$$

(b)

For  $f_i(s_i)$ , we will choose a Bernoulli approximation:

$$\tilde{f}_i(s_i) = \lambda_i^{s_i} + (1 - \lambda_i)^{1 - s_i}$$

Thus,

$$\log \tilde{f}_i(s_i) \propto \log \left(\frac{\lambda_i}{1-\lambda_i}\right) s_i$$

For  $g_{ij}(s_i, s_j)$ , we will choose a product of Bernoulli's approximation:

$$\tilde{g}_{ij}(s_i, s_j) = (\theta_i^{s_i} + (1 - \theta_i)^{1 - s_i}) (\theta_j^{s_j} + (1 - \theta_j)^{1 - s_j})$$

Thus,

$$\log \tilde{g}_{ij}(s_i, s_j) \propto \log \left(\frac{\theta_i}{1 - \theta_i}\right) s_i + \log \left(\frac{\theta_j}{1 - \theta_j}\right) s_j$$

To derive the a message passing scheme, we first define:

$$q(\mathbf{s}) = \left(\prod_{i=1}^K \tilde{f}_i(s_i)\right) \left(\prod_{i=1}^K \prod_{j=1}^{i-1} \tilde{g}_{ij}(s_i, s_j)\right)$$

Thus, we can derive cavity distributions:

$$q_{\neg \tilde{f}_{i}(s_{i})}(\mathbf{s}) = \left(\prod_{i'=1, i' \neq i}^{K} \tilde{f}_{i'}(s_{i'})\right) \left(\prod_{i=1}^{K} \prod_{j=1}^{i-1} \tilde{g}_{ij}(s_{i}, s_{j})\right)$$

and

$$q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) = \left(\prod_{i'=1}^K \tilde{f}_{i'}(s_{i'})\right) \left(\prod_{i'=1}^K \prod_{\substack{j'=1\\i', j' \neq i, j}}^{i'-1} \tilde{g}_{i'j'}(s_{i'}, s_{j'})\right)$$

For  $\tilde{f}_i(s_i)$ , we do not need to make an approximation step. This is because we are minimising:

$$\tilde{f}_i(s_i) = \arg\min \mathbf{KL} \left[ f_i(s_i) q_{\neg \tilde{f}_i(s_i)}(\mathbf{s}) \| \tilde{f}_i(s_i) q_{\neg \tilde{f}_i(s_i)}(\mathbf{s}) \right]$$

We know that the factor  $\log f_i(s_i)$  is a Bernoulli of the form  $b_i s_i$ . Because our approximation is also Bernoulli, we can simply solve for  $\lambda_i$  in  $\log \tilde{f}_i(s_i)$ :

$$\log \tilde{f}_i(s_i) = \log f_i(s_i)$$

$$\log\left(\frac{\lambda_i}{1-\lambda_i}\right)s_i = b_i s_i$$

$$\lambda_i = \frac{1}{1 + \exp(-b_i)}$$

On the other hand, for  $\tilde{g}_{ij}(s_i, s_j)$ , we will approximate with:

$$\tilde{g}_{ij}(s_i, s_j) = \arg\min \mathbf{KL} \left[ g_{ij}(s_i, s_j) q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) \| \tilde{g}_{ij}(s_i, s_j) q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) \right]$$

Note that because  $\tilde{g}_{ij}(s_i, s_j)$  is the product of two Bernoulli distributions, we only require the natural parameters:

$$\phi_{ij}(\theta) = \begin{bmatrix} \theta_i \\ \theta_j \end{bmatrix}$$

the mean with respect to  $s_i$  and  $s_j$  respectively.

We can write:

$$\log \tilde{g}_{ij}(s_i, s_j) q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) \propto \log \left(\frac{\theta_i}{1 - \theta_i}\right) s_i + \log \left(\frac{\theta_j}{1 - \theta_j}\right) s_j + \sum_{i'=1}^K \log \left(\frac{\lambda_{i'}}{1 - \lambda_{i'}}\right) s_{i'} + \sum_{i'=1}^K \sum_{\substack{j'=1\\i',j' \neq i,j}}^{i'-1} \log \left(\frac{\theta_{i'}}{1 - \theta_{i'}}\right) s_{i'} + \log \left(\frac{\theta_{j'}}{1 - \theta_{j'}}\right) s_{j'}$$

Only including terms with  $s_i$  and  $s_j$ :

$$\log \tilde{g}_{ij}(s_i, s_j) q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) \propto \left( (K - 1) \log \left( \frac{\theta_i}{1 - \theta_i} \right) + \log \left( \frac{\lambda_i}{1 - \lambda_i} \right) \right) s_i + \left( (K - 1) \log \left( \frac{\theta_j}{1 - \theta_j} \right) + \log \left( \frac{\lambda_j}{1 - \lambda_j} \right) \right) s_j$$

Moreover:

$$\log g_{ij}(s_i, s_j) q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) \propto \frac{-\mu_i^T \mu_j}{\sigma^2} s_i s_j + \sum_{i'=1}^K \log \left(\frac{\lambda_{i'}}{1 - \lambda_{i'}}\right) s_{i'} + \sum_{i'=1}^K \sum_{\substack{i'=1 \ i', j' \neq i, j}}^{i'-1} \log \left(\frac{\theta_{i'}}{1 - \theta_{i'}}\right) s_{i'} + \log \left(\frac{\theta_{j'}}{1 - \theta_{j'}}\right) s_{j'}$$

Only including terms with  $s_i$  and  $s_i$ :

$$\log g_{ij}(s_i, s_j) q_{\neg \tilde{g}_{ij}(s_i, s_j)}(\mathbf{s}) \propto \frac{\neg \mu_i^T \mu_j}{\sigma^2} s_i s_j + \left( (K - 2) \log \left( \frac{\theta_i}{1 - \theta_i} \right) + \log \left( \frac{\lambda_i}{1 - \lambda_i} \right) \right) s_i + \left( (K - 2) \log \left( \frac{\theta_j}{1 - \theta_j} \right) + \log \left( \frac{\lambda_j}{1 - \lambda_j} \right) \right) s_j$$
